

# REST

[ian.mcloughlin@gmit.ie](mailto:ian.mcloughlin@gmit.ie)

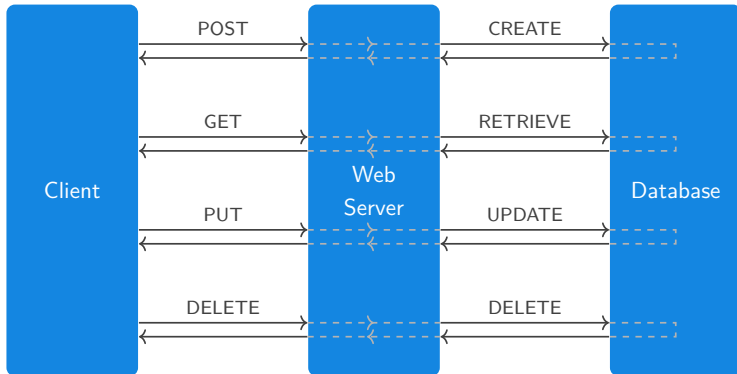

# HTTP APIs

- Facebook, Google, Reddit and others often provide programmable interfaces to their services.
- This lets other application developers use the services programmatically.
- For instance, Reddit allows developers to create mobile apps for viewing and making submissions to reddit.
- HTTP is often the mechanism used for this purpose.
- Access is provided through a set of URLs, across a variety of HTTP methods.
- The APIs often require JSON in HTTP request bodies and often return the query results as JSON.

# REST

- REST stands for Representational State Transfer.
- REST is an architecture describing how we might use HTTP.
- RESTful APIs make use of more HTTP methods than just GET and POST.
- Most HTTP APIs are not RESTful.
- RESTful APIs adhere to a few loosely defined constraints.
- Two of those constraints are that the API is stateless and cacheable.

# HTTP and CRUD

# AMP

## Typical example

Suppose we have a system for storing and retrieving emails.

Method	URL	Description
GET	/emails	list all emails
POST	/email	store new email
GET	/email/32	retrieve email with id 32
PUT	/email/32	update email with id 32
DELETE	/email/32	delete email with id 32

# Stateless

- Statelessness is a REST constraint.
- HTTP uses the client-server model.
- The server should treat each request as a single, independent transaction.
- No client state should be stored on the server.
- Each request must contain all of the information to perform the request.

# Cacheable

- REST APIs should provide responses that are cacheable.
- Intermediaries between the client and server should be able to cache responses.
- This should be transparent to the client.
- Cacheability increases response time.
- Browsers usually cache resources, in case they are requested again.
- There is usually a time limit on cached resources.

# CouchDB

- CouchDB is a document-oriented database.
- Documents are represented in CouchDB as JSON objects.
- Each document has its own id and revision, indicated by properties `_id` and `_rev` in the JSON document.
- Updating a document leaves its `_id` intact, but updates its `_rev`.
- Different documents can have different properties – there is no schema.
- The main interface with CouchDB, for storage and retrieval is a HTTP API.
- CouchDB uses HTTP methods such as `GET`, `POST`, `PUT` and `DELETE` to retrieve, add, update and delete documents.

# NoSQL

- NoSQL is the umbrella term for databases that do not conform to the relational, SQL-style model.
- Relational databases are good for some types of data.
- However, they have some issues.
- SQL queries can result in costly joins.
- Tables can be sparsely populated.
- Two common NoSQL database types are Document-oriented and Graph.

# Futon

- CouchDB has an in-built admin interface.
- It's called Futon.
- You access it through the `/_utils` path.
- You can create and delete databases.
- You can also create, update and delete documents.

# MapReduce

- MapReduce is a way of programming.
- It is a model for performing specific types of problems that are common in programming.
- MapReduce promotes algorithms that have an initially embarrassingly parallel part, and a subsequent consolidation part.
- The former is the Map part, and the latter is the Reduce part.
- MapReduce isn't necessarily anything new, the ideas have existed for a long time.
- The formalisation of those ideas and their implementation in systems such as Hadoop is useful.

# Map

Map takes a function and a list, and applies the function to every element of the list.

```
function map(fn, a) {  
  r = [];  
  for (i = 0; i < a.length; i++)  
    r[i] = fn(a[i]);  
  return r;  
}
```

# Reduce

Reduce takes the output of Map, and accumulates the elements in some way.

```
function reduce(fn, a, init) {  
  var s = init;  
  for (i = 0; i < a.length; i++)  
    s = fn(s, a[i]);  
  return s;  
}
```

## Map Reduce in CouchDB

Reduce takes the output of Map, and accumulates the elements in some way.

```
function(doc) {  
    if(doc.date && doc.title) {  
        emit(doc.date, doc.title);  
    }  
}  
  
function(keys, values, rereduce) {  
    if (rereduce)  
        return sum(values);  
    else  
        return values.length;  
}
```

<http://guide.couchdb.org/draft/views.html>

# Security

- HTTP is not encrypted.
- HTTPS is a protocol based on HTTP, but it provides security.
- GET and POST are by far the most commonly used HTTP methods (by web developers).
- Data sent by GET and POST will be encrypted over HTTPS.
- However, it's generally accepted that POST is more secure for sending sensitive data.
- This is because browsers will typically cache and servers will typically log URLs, with the data encoded in them.

# HTTP access control (CORS)

**cross-origin** HTTP requests occur when a resource makes a request from a different domain than it was served from.

**img** tags often do this – for example, an image might be included from a photo sharing service.

**css and js** files are also often served from domains different from the original.

**Browsers** usually restrict cross-origin requests initiated by scripts.
